

Implementation strategies: implementation planning

Lesson

Learning Objectives

Over the next course you will learn how to:

- Develop supporting measures through an option generating tool
- Build a spatial clustering and temporal sequencing of measures (implementation timeline)

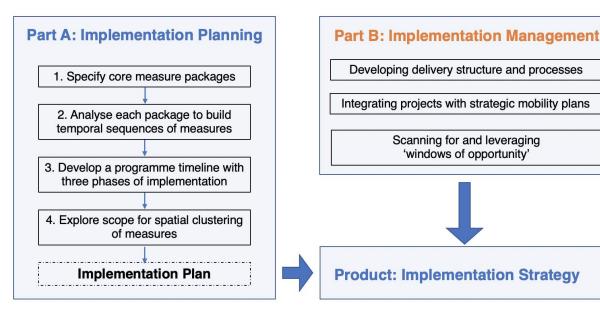

Implementation strategy concept

- Part A: Implementation Planning a recommended process for planning measure implementation in a sequential series of four steps, to produce a list of core measure packages, an implementation timeline and a spatial overview of implementation. Combined, these elements form an Implementation Plan.
- Part B: Implementation Management a flexible set of organisational approaches for managing measure implementation.

The end product is an Implementation Strategy, with the core contents of the Implementation Plan produced through the Part A process, complemented by potential description of approaches drawing on Part B.

Part A: Implementation planning

Step 1: Specifying core measure packages

The first step of developing an Implementation Strategy is to specify the measures to be implemented as holistic packages of the most important 'core' measures and 'supporting' measures that provide positive synergies or make the implementation of the core measure technically/practically feasible

Step 1 involves three activities:

- Defining individual core measures
- Identifying supporting measures
- Finalising core measure packages

A core measure is one of the 'key' or most significant urban mobility measures to be implemented in a city.

If a city has developed a SUMP, measures will already have been subject to careful consideration and described in some detail to enable appraisal, and then incorporated into integrated measure packages seeking to provide a balanced mix of measure. Thus, where a SUMP already exists, then the core measures for an Implementation Strategy can simply be defined by analysing what the 'key' measures are within finalised measure packages (defined in Step 7 of the SUMP cycle) – cities will have an intuitive feel for what the most significant planned interventions are.

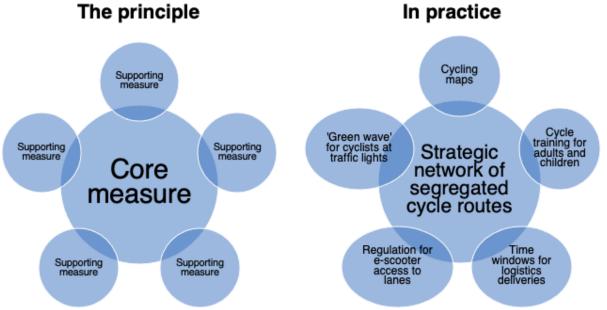

CIVITAS SUMP-PLUS

Most 'core' measures are likely to benefit from the introduction of a number of 'supporting' measures that make implementation technically/feasible possible, or that provide positive synergies by enhancing the effectiveness of core measures

1.2. Identifying supporting measures

In order to identify synergies, a matrix was developed within SUMP PLUS that can enable cities to brainstorm by following a used and tested methodology. The rows of the matrix describe four types of policy measures (physical, pricing, regulation and information) and the columns six areas of implementation (from public/collective transport to land use and public space).

Example

Core measure: Bus with High Level of Service

Components of 'core' measure Potential 'supporting' measures

TYPE OF	CORE MEASURE	SUPPORTING MEASURES						
MEASURE	Public/ Collective transport	Walking/ Cycling/ Micro-mobility	Private vehicle ownership/use	Urban Freight and Logistics	Traffic/Kerbside Management	Land Use and Public Space		
Physical (infrastructure, operations)	 Bus lanes and signal priority Bus shelters and seating CCTV to improve on-board safety 	 Improved infrastructure in bus stop catchment area; Safer crossings to stops 	 Park & Ride provision at key stops/interchan ges 	 E- lockers at major bus interchange 	 Kerb build-outs and raised platforms at bus stops to enhance boarding 	 Concentrate development around major interchanges New public spaces 		
Pricing (fares, charges, incentives)	 Payment system with pre-boarding or quick on-board payment 				 Higher parking charges in the city centre 			
Regulation (space, time, type)	 Electric vehicles Low-floor buses 	 Designate cycle and e-scooter parking spaces close to bus stops 	 Designate city centre as ultra- low emission zone 	 Time windows for kerbside goods deliveries along routes 	 Camera-based enforcement of bus lanes Restrict parking along bus corridors 	 Planning for provision of health and library services close to bus interchanges 		
Information (ICT-enabled, marketing)	 Dedicated website Real-time information displays at bus stops 	 On-street signage to bus stops 	 Campaign targeting car commuters to switch to bus 	 Awareness campaign about bus lane rules 			IVITAS	

1.3. Finalise core measure packages

To complete Step 1, an overview description – for example, a list – of core measure packages can be assembled. In line with the general structure in the table below, this includes several core measure packages, each consisting of one core measure and several supporting measures (following the example of the table before...)

Core measure package	Core measure component	Supporting measures
Package 1 – Improving public transport infrastructure	Core measure component 1: Bus lanes and signal priority	Supporting measure 1.A: Safer crossings at stops
[short description]	Core measure component 2: Bus shelters and seating	Supporting measure 1.B: Designated e-scooters and shared mobility parking spaces near public transport stops
	Core measure component 3: Real time information and ticketing	Supporting measure 1.C: E-lockers at major bus interchanges
	Etc	Supporting measure 1.D: On street signage
		Etc

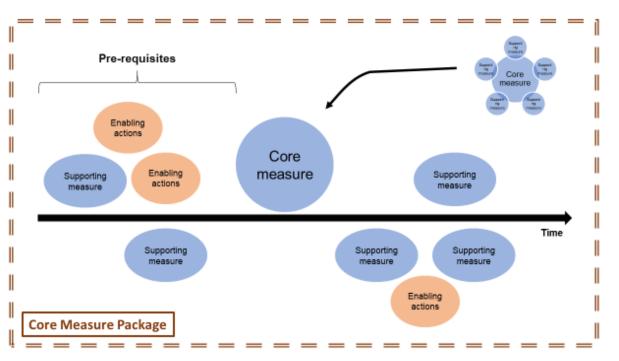

2. Analyse each package to build a temporal sequence of measures

Once the set of core measure packages has been defined, the next step is to determine how implementation will be phased over time. This is referred to as 'temporal sequencing' – in what order, measures and other actions will be taken.

There are two factors to take into account for measure sequencing:

- Pre-requisites that make measure implementation possible: actions that have to be taken before other actions – 'what comes first' due to interdependencies
- Strategic and pragmatic considerations for 'what comes first'

Analysing pre-requisites: 'what comes first' due to interdependencies

Pre-requisites include both supporting measures (physical, pricing, regulatory, or information) and enabling actions (institutional, financial) that need to be implemented *prior to* implementation of a core measure.

- **Physical pre-requisites**, e.g. the need to widen a road to in order to implement a bus priority lane without removing general traffic capacity; or, to install electric charging points before encouraging local EV purchase. Some of these pre-requisites will include *supporting measures* identified within Step 1.
- Ensuring adequate **enforcement mechanisms** are in place for measures involving regulations, e.g. camera-based enforcement being available prior to implementation of bus priority lanes or speed limits.
- Enabling actions are actions that are necessary to enable implementation of policies, but are not measures in themselves. This includes actions to affect institutional change (e.g. new institutional capacities, modified institutional frameworks, acquiring new local powers) or secure financial resources through new funding and financing mechanisms.

Strategic and pragmatic considerations for 'what comes first'

In addition to the effectiveness-related considerations discussed above, measure sequencing can also be approached from a strategic and pragmatic perspective. Core and supporting measures can be analysed by considering the following factors:

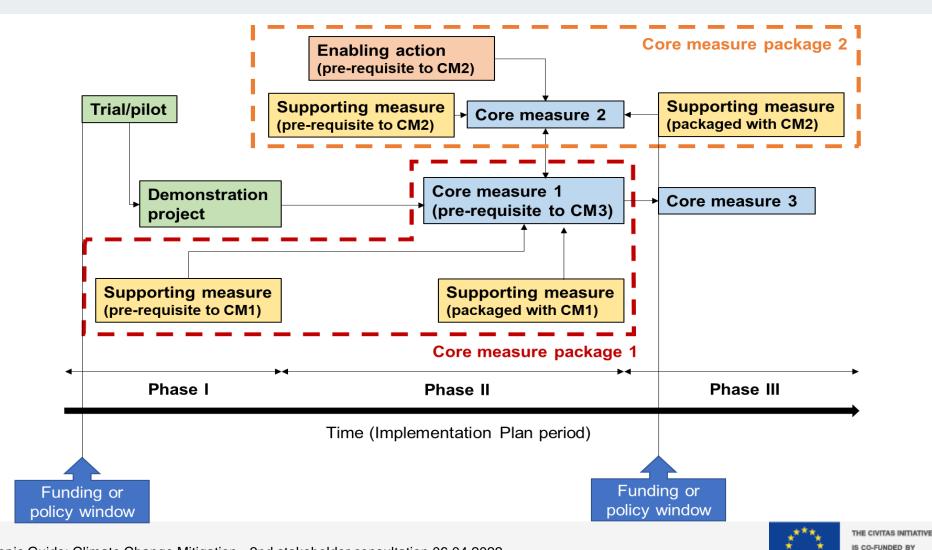

- **Measure Maturity Level** how mature is the measure (next slide)?
- **Cost of implementation** is the measure potentially low-cost or inherently expensive? This includes considering whether initial implementation using temporary, low-cost materials is possible and appropriate (see section 3.3.4) and in general, trying to be creative in the face of resource constraints.
- **Feasible speed of implementation** how quickly can the measure be implemented?
- **Reversibility and adaptability** how reversible or adaptable is the measure, once implemented? Can the measure be implemented as a temporary intervention (e.g. trial/pilot) or does it require relatively permanent intervention? Is it a measure that can be implemented with 'no regrets', or may it potentially create a path-dependency?
- Public acceptability how controversial is the measure, is there sufficient political momentum for the measure to be implemented?

Components of temporal sequencing

THE EUROPEAN UNION

Indicative timing for each core measure package

Once the three factors described above have been considered, an indicative timeline for each core measure package can be constructed. This will need to be adjusted once the implementation of this package is considered in relation to other core packages within the Implementation Plan. Information could be collated within an Excel spreadsheet, e.g. indicate using Gantt charts to sequencing.

Measures that are implemented first, because they are:

- Low Maturity Level testing novel measures
- Low cost / resources are available
- Quick to implement: do not involve permanent infrastructure or construction (e.g. regulatory, information measures)
- Reversible and adaptable, thus not requiring extensive appraisal
- Can be implemented through temporary intervention (trial/pilot)
- Have a higher level of public acceptability

Measures that are implemented later, because they are:

- High Maturity Level refinement, further appraisal has created confidence
- Expensive / resources not available
- Slow to implement: involve infrastructure and construction
- Non-reversible, at least not easily; cannot be implemented through temporary intervention

Sequence of implementation

 Have lower levels of public acceptability, so momentum must be built

Time

Step 3: Develop a programme timeline with three phases of implementation

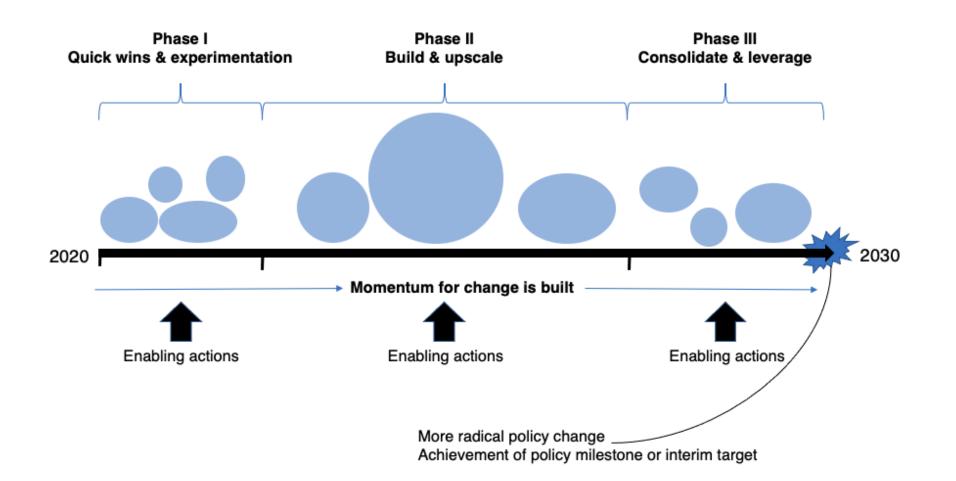

Across the programme of core measure packages, we divide the 5 to 10-year implementation period into three phases

- Quick wins & experimentation an initial, shorter phase where momentum starts to be built through 'quick wins', and of testing new solutions/refining measure design through trials. This will include pre-requisites and smaller supporting measures that are quick to implement. Activities to prepare for Phase II will also need to be undertaken, e.g. planning of major projects.
- Build & upscale a 'middle', longer phase where larger-scale (typically 'core') measures and investments, that have taken more time to prepare for, are implemented, including physical construction of infrastructure. During this phase, measures that were tested in Phase I are either integrated into core measure design or upscaled. Momentum continues to build, as significant new travel options are made available to people in the city. Implementation of 'quick win' measures may continue, if available.
- **Consolidate & leverage –** a final phase, where the focus is on consolidating what has been achieved through further enhancing effectiveness of measures, including synergistic supporting measures. This includes in particular information-oriented measures seeking to promote new infrastructure and services implemented in Phase II. The momentum that has been built is leveraged to implement measures that were controversial initially. Towards the end of the period, built-up momentum allows for a push towards a more radical change in policy, resulting in achievement of an ambitious policy milestone or interim target.

Step 3: Develop a programme timeline with three phases of implementation

Step 4: Explore scope for spatial clustering of measures

Once implementation has been planned over a time period, a further step is to explore implementation in relation to urban space, by considering the scope for spatial clustering of different measures. A cluster means a group of similar things positioned or occurring closely together. Spatial clustering will definitely apply to a core measure and its supporting measures, but clustering of different core measures might also be relevant. The spatial clustering in this section is designed to promote a space-based thinking approach in order to organise existing or possible measures. Spatial considerations should be taken into account also at the beginning of the analysis of any transport related measure.

Some measures naturally apply across a whole administrative area (e.g. revised fare tariffs for public transport), but most are implemented in specific areas, even where they are planned as part of an extensive programme.

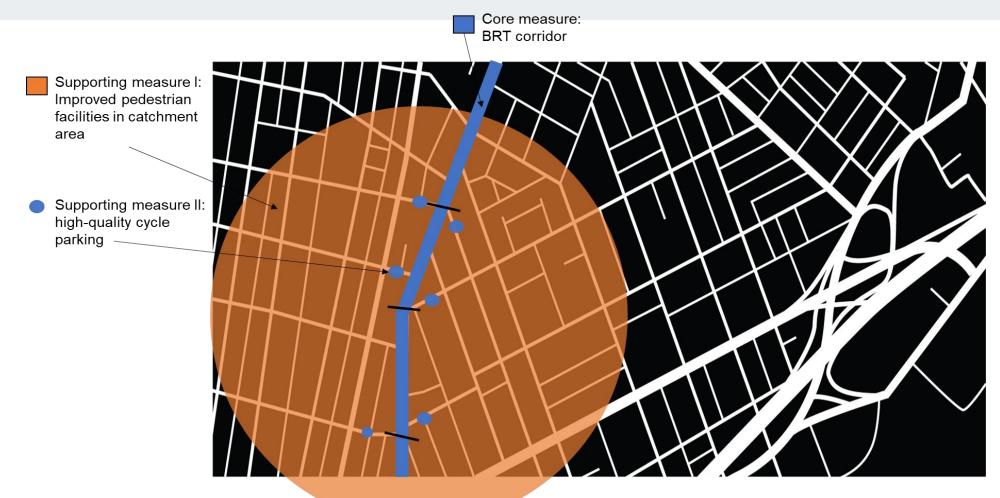

There are four spatial aspects to consider:

- What are the appropriate spatial units for implementation?
- How are priority areas for implementation selected?
- What benefits can be derived from spatial clustering of measures?
- How to manage spatial roll-out, over time?

Spatial clustering – the concept

SUMP Topic Guide: Climate Change Mitigation - 2nd stakeholder consultation 06.04.2022

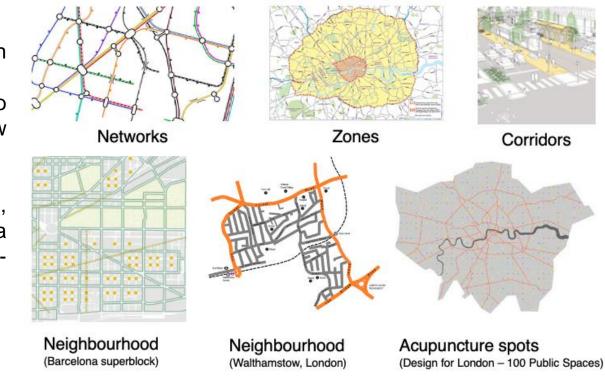

Step 4: Spatial units for implementation - 1

The type of spatial unit used for implementation will depend on the type of core measure, but relevant units include (see Figure 6.15):

- Networks: for rail, bus or cycle infrastructure
- Corridors: e.g. for bus priority schemes or 'green waves' for smoothing traffic flow
- Zones, usually based on technical criteria, to address a specific problem: controlled parking or low emission zones, low speed limit zones

For example, for a core measure of bus service upgrades, this could be achieved through a network approach, a corridor approach; or by focusing on introducing lowemission vehicles within a particular zone.

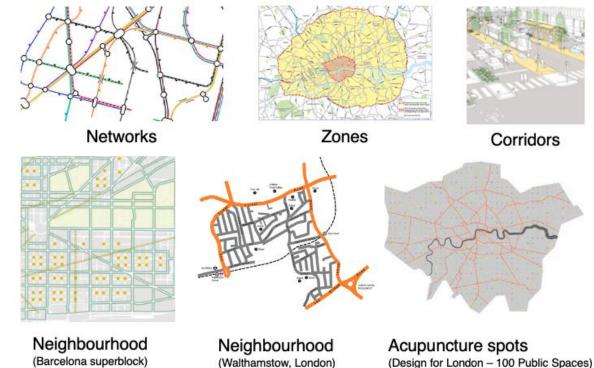

Step 4: Spatial units for implementation - 2

Other types of spatial approaches include:

- Neighbourhoods: for community-level initiatives, such as the Barcelona 'superblocks', or low-traffic neighbourhoods (e.g. Walthamstow 'Mini-Holland' in London)
- 'Acupuncture' spots: small interventions dotted around a city, such as the development of public spaces through dispersed intervention, 'shaving off' vehicle road space for reallocation to public life. Examples include Design for London's 100 Public Spaces programme and the New York City Department of Transportation's Public Plaza Program.

Creating a visual overview of implementation: integrating temporal and spatial dimensions: Creating a series of maps and diagrams that provide a clear visual overview of what areas of the city, or using what spatial units, your measures will be implemented, will add value to your Implementation Strategy. It will be particularly useful to provide a clear picture of how the Implementation Plan will be rolled out, over time.

The end product of the Part A process is an Implementation Plan, containing:

- a list of core measure packages
- an implementation timeline
- a spatial overview of implementation

Activity: supporting measures

Step 1. Take your current SUMP or the one your city is developing. Consider your SUMPs objectives and add them to the table. You will see there are **sample objectives** in it now (measures promoting public transport, walking and cycling, etc).

Objectives guiding the selection of policy measures

Objective 1: Measures promoting the use of	Core
Public Transport	Supporting
Objective 2: Measures promoting walking and public space	Core Supporting
Objective 3: Measures promoting cycling	Core Supporting
Objective 4 : Measure promoting car use	Core
reduction	Supporting
Objective 5: Measure promoting	Core
multimodality / overarching	Supporting

Process to complete policy measure tables

A. Identify and categorize **CORE MEASURE COMPONENTS**. Use the long list of projects (usually each city has one from previous SUMP or the current one). Select prioritized core measures from each objective and use the SUMP-PLUS matrix to categorize them (see "Supporting Public Transport" example). **Complete Activity A.**

B. Identify and categorize **SUPPORTING MEASURES**. Use the long list of projects and select those supporting measures that were prioritized. If you haven't got a prioritization yet, add all that you think would somehow enhance the core measure (in the example they would be those that support public transport). For now concentrate on those measures or projects that are already in discussion. Input the supporting measures in the extended version of the SUMP-PLUS matrix, which has additional columns (see "Supporting Public Transport" example, B). NOTE that:

- The supporting measures for each objective could fit in any of the matrix columns and rows

- You need to complete a supporting measures table for each of the five objectives

Complete Activity B.

C. Brainstorm **POSSIBLE ADDITIONAL SUPORTING MEASURES**. After the previous step, you will find some cells in the matrix that are blank (those with '?' in the "Supporting Public Transport" example, C1). Consider gathering with colleagues from other departments and convene a workshop to think about other supporting measures that could be applied in your city (for example colleagues from the Urbanism and Architecture department, public space department, energy and services, education, etc). Input additional feasible supporting measures; these might be in development, planned or completely innovative ideas. **Complete Activity C**.

A. Objective 1: Measures promoting the use of Public Transport (core measure components from long list to put into the SUMP-PLUS matrix)

	Core measure					
Type of measure	What measures Promoting the use of Public transport are related to?	Promoting walking and public space	Promoting cycling	Promoting a reduction of private car use	Promoting multimodality and others	
Physical (infrastructure, operations)	 Priority bus lane (segregated) Pedestrian crossings to bus stops Bus shelters/ interchange stations Spacing between bus stops 					
Pricing (fares, charges, incentives)						
Regulation (space, time, type)	- Relocation of parking spaces along bus route					
Information (ICT enabled, marketing)	- Real-time information					
					**** THE	

THE CIVITAS INITIATIVE

B. Objective 1: Supporting measures promoting the use of Public Transport

Guidance question: are there any measures related to public transport, walking, cycling, private cars, freight, traffic management and land use planning that could support the objective to promote public transport?

THE CIVITAS INITIATIVE IS CO-FUNDED BY THE EUROPEAN UNION

C. Objective 1: Additional supporting measures promoting the use of Public Transport; copy B2 and add..

Guidance: Come up with some additional ideas for supporting measures. In the table below in red some example of supporting measures that could apply for the promotion of the use of public transport. Not all cells need to be completed - they are there to stimulate thinking.

Type of measure	Additional Supporting Measures: Are there any additional ideas for projects you can think of in the areas of walking, cycling, private car use, freight, traffic management, land use, that could help with the objective of supporting public transport? In this table some new ideas are represented in red.						
	Public transport	Walking	Cycling	Private car use	Freight and log	Traffic management	Land use & public space
Physical (infrastructure , operations)	Electric bus vehicles	?	Bike and ride (docking stations at bus stops - multimodality) Dedicated cycle lanes, segregated by kerbs Lights at intersections (cycle lanes)	?	?	CCTV (only at intersections) Stop light management (upgrade)	Park and ride Lighting programme Pedestrian sensors (lights)
Pricing (fares, charges, incentives)	E-ticketing Concessionary fares (High school – retired)	?	?	Charges for violation of priority lane	Charges for violation of priority lane	Communication system in place to issue charges (upgrade)	Parking managemen t (plan to design a policy)
Regulation (space, time, type)	?	?	?	Exception for properties along the bus lane corridor	?	Enforcement of parking restrictions along bus routes	Land use regulation for side walks and frontages
Information (ICT enabled, marketing)	Integration into digital information platform Passenger information (Bus stations /online) Intelligent map for tourism		?	?	?	?	? THE CIVITAS INTIA IS CO-FUNDED BY
